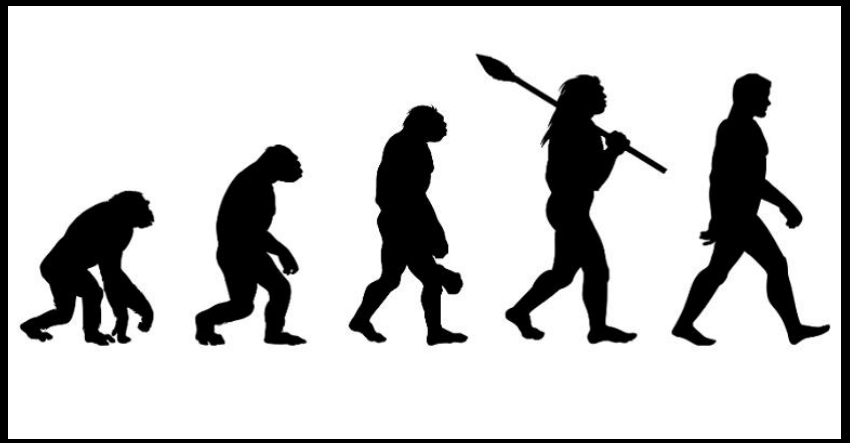
THEORY OF EVOLUTION

Charles Darwin

EVOLUTION AND ADAPTATION

Evolution, is the development of animals and plants from earlier or simpler forms of life . This is also the gradual change of change into something else. Also, evolution also links on the fact of inheritance in the way of adapting to environment or adapting to were they live. This theory was said by Charles Darwin and his partner [not in marriage] Alfred Wallace .This theory, has been proven by scientists around the world and everyday animals go through this process such animals every day need to adaptation even when their habitat is being destroyed



NATURAL SELECTION

Natural selection, is the differential survival and reproduction of individuals due to differences in phenotype. It is a key mechanism of evolution, the change in the heritable traits characteristics of a population over generations . It is also the process before evolution . It is the important agent of evolutionary change, simply because it results in adaptation of an organism to its environments.
